Ionotropic receptors as the driving force behind human synapse establishment

Supplementary Material

Lucas H. Viscardi Danilo O. Imparato Maria Cátira Bortolini Rodrigo J. S. Dalmolin

6 Abstract

The origin of nervous systems is a main theme in biology and its mechanisms are largely underlied by synaptic neurotransmission. The search for pan-neuronal genes has failed to explain synapses emergence since synaptic elements are present in multiple aneural organisms. We questioned how the interactions among these elements evolved and to what extent does it relate to our understanding of the nervous systems complexity. We infer the human neurotransmission gene network based on genes present in GABAergic, glutamatergic, serotonergic, dopaminergic, and cholinergic systems, and reconstruct the evolutionary scenario of synapse emergence. Our results outline the distribution of neurotransmitter systems and synaptic functions as taxa diverge. We find that the ionotropic receptors emergence in the cuidarian last common ancestor was the driving force behind the advent of the anatomical synapse and the development of nervous systems. We suggest that after Placozoa origin there was a positive selection under a more restricted and specific activation of ionotropic receptors. This different selective pressure counterparting the broader amino acid activation in plants could be striking for the evolution of the nervous system.

Project structure

55 This is the title page

56 Preprocessing

This topic refers mainly to data wrangling done before the actual analysis with the intent of making it simpler.

59 Eukaryota species tree

- We opted to use the TimeTree database in order to obtain an standardized Eukaryota species tree. However,
- 51 some species were not present in it, so we devised a way to fill them in based on NCBI Taxonomy data.

NCBI Taxonomy tree

First we preprocess NCBI Taxonomy data to leave only STRING eukaryotes, thus making the task easier.

4 Resources

65

Table 1: Lists all organisms in STRING v11.

	string_species									
#	Col. name	Col. type	Used?	Example	Description					
1	taxid	character	yes	9606	NCBI Taxonomy identifier					
2	string_type	character	no	core	if the genome of this species is core or periphery					
3	string_name	character	yes	Homo sapiens	STRING species name					
4	$ncbi_official_name$	character	no	Homo sapiens	NCBI Taxonomy species name					

Location: data-raw/download/species.v11.0.txt

Source: stringdb-static.org/download/species.v11.0.txt

Table 2: Links outdated taxon IDs to corresponding new ones.

	ncbi_merged_ids									
#	Col. name Col. type Used? Example				Description					
1	taxid	character	yes	140100	id of node that has been merged					
2	${\it new_taxid}$	character	yes	666	id of node that is the result of merging					

Location: data-raw/download/taxdump/merged.dmp

Source: ftp.ncbi.nlm.nih.gov/pub/taxonomy/taxdump.tar.gz

Table 3: Represents taxonomy nodes.

	ncbi_edgelist							
#	Col. name	Col. type	Used?	Example	Description			
1	taxid	character	yes	2	node id in NCBI taxonomy database			
2	parent_taxid	character	yes	131567	parent node id in NCBI taxonomy database			
3	rank	character	no	superkingdom	rank of this node			
4			no		(too many unrelated fields)			

Location: data-raw/download/taxdump/nodes.dmp

Source: ftp.ncbi.nlm.nih.gov/pub/taxonomy/taxdump.tar.gz

Table 4: Links taxon IDs to actual species names.

				ncbi_taxon_names			
#	Col. name	ol. name Col. type Used? Example		Description			
1	taxid	character	yes	2	the id of node associated with this name		
2	name	character	yes	Monera	name itself		
3	unique_name	character	no	Monera dacteria>	the unique variant of this name if name not unique		
4	$name_class$	character	yes	scientific name	type of name		

Location: data-raw/download/taxdump/names.dmp

Source: ftp.ncbi.nlm.nih.gov/pub/taxonomy/taxdump.tar.gz

66

7 Updating STRING taxon IDs

- 68 Some organisms taxon IDs are outdated in STRING. We must update them to work with the most recent
- 69 NCBI Taxonomy data.

```
string_species %<%
left_join(ncbi_merged_ids) %>%
mutate(new_taxid = coalesce(new_taxid, taxid))
```

• Creating tree graph

The first step is to create a directed graph representing the NCBI Taxonomy tree.

```
# leaving only "scientific name" rows
ncbi_taxon_names %令%
  filter(type = "scientific name") %>%
  select(name, ncbi_name)

# finding Eukaryota taxid
eukaryota_taxon_id ← subset(ncbi_taxon_names, ncbi_name = "Eukaryota", "name", drop = TRUE)

# creating graph
g ← graph_from_data_frame(ncbi_edgelist[,2:1], directed = TRUE, vertices = ncbi_taxon_names)

# easing memory
rm(ncbi_edgelist, ncbi_merged_ids)
```

72 Traversing the graph

- 73 The second step is to traverse the graph from the Eukaryota root node to STRING species nodes. This
- ⁷⁴ automatically drops all non-eukaryotes and results in a species tree representing only STRING eukaryotes
- 75 (476).

76 Saving

- 77 Saving ncbi_tree and string_eukaryotes for package use. These data files are documented by the package.
- We also create a plain text file 476_ncbi_eukaryotes.txt containing the updated names of all 476 STRING
- eukaryotes. This file will be queried against the TimeTree website.

```
ncbi_tree 		 treeio::as.phylo(eukaryote_tree)
# plot(ncbi_tree %>% ape::ladderize(), type="cladogram")

string_eukaryotes 		 string_species %>%
    filter(new_taxid %in% ncbi_tree$tip.label) %>%
    inner_join(ncbi_taxon_names, by = c("new_taxid" = "name"))

write(string_eukaryotes[["ncbi_name"]],"476_ncbi_eukaryotes.txt")
# usethis::use_data(ncbi_tree, overwrite = TRUE)
write.tree(ncbi_tree, "tree_ncbi.nwk")
usethis::use_data(string_eukaryotes, overwrite = TRUE)
```

```
## <U+2714> Setting active project to 'C:/R/neuro'
```

B1 ## <U+2714> Saving 'string_eukaryotes' to 'data/string_eukaryotes.rda'

82 Duplicated Genera

- 83 Some species from different kingdoms may share the same genus name. These genera must be noted down
- because one of the ways we fill in missing species is by looking at genera names. For taxid_rank and
- ncbi_taxon_names see Table 3 and Table 4, respectively.

```
# keeping genera nodes
taxid_rank % % filter(rank = "genus")

# keeping scientific names
ncbi_taxon_names % %
filter(type = "scientific name") % > %
select(taxid, ncbi_name) % > %
inner_join(taxid_rank)

# extracting and saving duplicated values
duplicated_genera ← ncbi_taxon_names % > %
pull(ncbi_name) % > %
extract(duplicated(.)) % > %
write("duplicated_genera.txt")
```

86 Hybrid tree

- Once we have both the NCBI eukaryotes tree and the list of duplicated genera, we can start assembling the
- 88 complete hybrid tree.

89 Resources

- Besides downloading all TimeTree species data (Eukaryota_species.nwk) we also need to manually query the website for the 476 STRING eukaryotes (476_ncbi_eukaryotes.txt). The file is called 476_ncbi_eukaryotes.txt because it contains updated NCBI Taxonomy names rather than STRING
- outdated names. This ensures better results.

- timetree_newick is the tree obtained by manually uploading 476_ncbi_eukaryotes.txt to the TimeTree
- website. tree_85k is the complete Eukaryota tree we have just downloaded.

```
# loading species names and taxon ids
load("../data/string_eukaryotes.rda")

# loading newick tree manually obtained from timetree
timetree_newick \( \simetize \text{read.tree}("download/timetree_335_eukaryotes.nwk")

# the following genera names are unreliable and should not be searched for
duplicated_genera \( \simetize \text{scan}("duplicated_genera.txt", \text{what = "character"})

# loading all TimeTree species data we have just download (85000 species)
tree_85k \( \simetize \text{read.tree}("download/Eukaryota_species.nwk")
```

6 Unfound species with matching genera

- Some of the 476 STRING eukaryotes are not present in the TimeTree database. However, sometimes TimeTree does contain tree data for closely related species (e.g. *Monosiga brevicollis* is not present, but
- 99 Monosiga ovata is). Therefore, we can use these closely related species as proxies for the actual species.
- This is done by searching for genera names in the complete database (Eukaryota_species.nwk). In the
- given Monosiga brevicollis example, we search for Monosiga in the complete database. We see that there is
- information for at least one other species of the *Monosiga* genus (in this case, *Monosiga ovata*), so we add
- Monosiga brevicollis as a sister branch to the found species.

When you search for a term in TimeTree, it uses a synonym list obtained from NCBI to try to resolve it.

Sometimes TimeTree will resolve a searched term to a scientific name different from the one you searched
for. The problem with this is that TimeTree does not make it obvious that it is returning a different term.

The first step is to find out which species resolved to different names in the timetree_335_eukaryotes.nwk
file:

Now we can start looking for unfound species genera in the complete tree data.

Once we figured out which species have proxy genera in the complete data, we can start filling them in as sister branches.

```
# for each unfound species which genus is present in the 85k tree,
for(i in 1:nrow(unfound_species)){
    # we search for all species of this genus ("sister species") in the 85k tree

# this part is tricky because bind.tip rebuilds the tree from scratch
# so we need to keep removing underscores. there are better mays to do this.

tip_genus ← tree_genus[["tip.label"]] %>% strsplit("[_]") %>% sapply("[", 1)

sister_species ← tree_genus["tip.label"]][tip_genus = unfound_species[[i, "genus_search"]]]
# we obtain the sister_species "most recent common ancestor (MRCA)
# c(.[1]) is a hack because the MRCA function only works with at least 2 nodes
where ← getMRCA(tree_genus, sister_species %>% c(.[1]))
# and then add a leaf node linked to this MRCA

tree_genus %
# for some reason bind.tip(tip.label = unfound_species[[i, "ncbi_name"]], where = where)

# for some reason bind.tip adds underscores to species names

tree_genus[["tip.label"]] %>% str_replace_all("_", "")

# keeping track of found species

found_species ← species_dictionary %>% filter(!is.na(timetree_name) | genus_search %in% tree_85k_genera)
# forced_name means it either was found in timetree or we forced it by looking at genera names

found_species %
# we keep only found species in this tree we are building (timetree + forced by genera)

# so we keep only found species in this tree we are building (timetree + forced by genera)

tree_genus %
# which found_species rows correspond to each tip.label?
match_tiplabel_name ← match(tree_genus[["tip.label"]], found_species[["forced_name"]])

tree_genus %
# kist_modify(
# converting to ncbi taxids

tip.label = found_species[["new_taxid"]][match_tiplabel_name]

)
```

5 Species of unfound genera

In this part, we try to fill in the remaining missing species (those which genera were not found in TimeTree) by searching for their closest relatives (according to NCBI Taxonomy) that are present in the current tree.

Once we find its two closest relatives, we can add the missing species as a branch from their LCA. This is a conservative approach.

```
# converting ncbi phylo to igraph
graph_ncbi ← read.tree("tree_ncbi.nwk") %>% as.igraph.phylo(directed = TRUE)

# converting phylo to igraph
graph_genus ← as.igraph.phylo(tree_genus, directed = TRUE)

# for each species which genus is not in timetree
# we'll look for its two closest species (in the NCBI tree) which are present in the tree genus we just built
unfound_genera ← species_dictionary %>% filter(is.na(timetree_name) & !genus_search %in% tree_85k_genera)

# this is the igraph equivalent of "phylo_tree$tip.label"
tip_nodes ← V(graph_ncbi)[degree(graph_ncbi, mode = "out") = 0]

# undirected distances between all species nodes
tip_distances ← graph_ncbi %>%
distances(v = tip_nodes, to = tip_nodes, mode = "all") %>%
as_tibble(rownames = "from") %>%
pivot_longer(-from, names_to = "to", values_to = "distance")

# removing self references (zero distances)
tip_distances %>% filter(distance > 0)

# we only want to search for species of unfound genera
tip_distances %>% inner_join(unfound_genera %>% select(from = new_taxid))

# we only want to find species already present in the genus_tree
tip_distances %>% inner_join(found_species %>% select(to = new_taxid))

# we only want to the two closest relatives
tip_distances %>% inner_join(found_species %>% select(to = new_taxid))

# we only want the two closest relatives
tip_distances %>% group_by(from) %>%
group_by(from) %>%
top_n(-2, distance) %>% # top 2 smallest distances
top_n(2, to) # more than 2 species have the same smallest distance, so we get the first ones
```

```
# out distance matrix between all nodes in tree, needed to find MMCAs
out_distances ← graph_genus %% distances(mode = "out")

# for each species of unfound genera,
# we find the MMCA for its two closest relatives
unfound_genera_mrca ← tip_distances %% group_by(from) %% summarise(mrca = {
# which ross have no infinite distances? the last one represents the MMCA
mrca_row_index ← max(which(rowSums(is.infinite(out_distances[, to])) = 0))

# adding unfound genera species nodes
# graph_genus %0% add_vertices(nrow(unfound_genera_mrca), color = "red", attr = list(name = unfound_genera_mrca[["from"]]))

# adding unfound genera species nodes
# adges_to_add(!) → edges_to_add(!) → edges_to_add(]) → edges_to_add(] → edges_to_add(!) → edges_to_add(!)

# connecting species leafs to the supposed MMCA
# graph_genus %0% add_edges(V(graph_genus)(edges_to_add!))

# plotting
# plotti
```

Ctenophora as sister to all animals

According to TimeTree, Ctenophora remains as a sister group to Cnidaria. We believe the most recent consensus in literature is to consider them a sister group to all animals. The following code block moves *Mnemiopsis leidyi*, the only ctenophore in our analysis, to the base of the metazoan lineage.

```
# moving ctenophora before porifera
mnemiopsis_taxid ← species_dictionary %>% filter(ncbi_name = "Mnemiopsis leidyi") %>% pull(taxid)
amphimedon_taxid ← species_dictionary %>% filter(ncbi_name = "Amphimedon queenslandica") %>% pull(taxid)

# reordering tip.labels
from_to ← c(
   "400682" = "27923", # amphimedon to mnemiopsis
   "10228" = "400682", # trichoplax to amphimedon
   "27923" = "10228" # mnemiopsis to trichoplax
)

modified_phylo ← phylo_graph_genus

modified_phylo[["tip.label"]] %<% recode(!!!from_to)
write.tree(modified_phylo, "../data/hybrid_tree_modified.nwk")</pre>
```

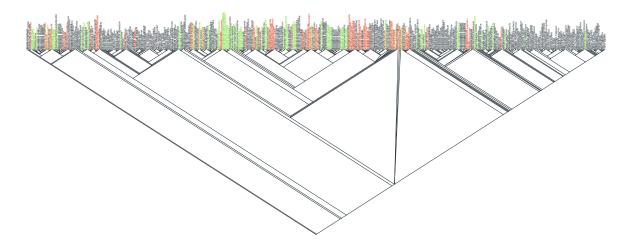

Figure 1: Complete 476 eukaryotes tree. Green species have been filled in by a genus proxy in TimeTree. Red species have been filled in by looking at NCBI Taxonomy.

Gene selection and annotation

- 125 The anchoring point for this study is basic annotation about genes and the pathways in which they partici-
- pate. This section describes the process of structuring such data. In the end we will have a table to which
- 127 all kinds of additional data will be left joined into.

Neurotransmitter systems annotation

We start by querying the KEGG api for the pathways of interest. Resulting data is then pivoted to a wider format.

Table 5: All links between genes and pathways in KEGG.

link_pathway_entrez									
#	Col. name	Col. type	Used?	Example	Description				
1	$entrez_id$	character	yes	hsa:10411	NCBI Taxonomy identifier				
2	$pathway_id$	character	yes	path: $hsa04726$	KEGG pathway ID				

Location: data-raw/download/link_pathway_entrez.tsv

Source: http://rest.kegg.jp/link/pathway/hsa

```
pivot_wider(
   id_cols = entrez_id,
   names_from = pathway_name,
   values_from = n,
   values_fn = list(n = length),
   values_fill = list(n = 0)
) %>%
   mutate(system_count = rowSums(select(., -entrez_id)))

# exporting for package use
usethis::use_data(gene_pathways, overwrite = TRUE)
```

131 ## <U+2714> Setting active project to 'C:/R/neuro'

2 ## <U+2714> Saving 'gene_pathways' to 'data/gene_pathways.rda'

	tail(gene_pathways)									
entrez_id	glutamatergic	cholinergic	serotonergic	gabaergic	dopaminergic	system_count				
805	0	0	0	0	1	1				
808	0	0	0	0	1	1				
810	0	0	0	0	1	1				
84152	0	0	0	0	1	1				
91860	0	0	0	0	1	1				
9575	0	0	0	0	1	1				

Base ID lookup table

Now we start building a base ID lookup table containing entrez gene IDs, STRING ensembl protein IDs, ensembl gene IDs, STRING protein names and entrez gene names. Every piece of data in subsequent analyses will be progressively joined to it.

Table 6: Conversion dictionary from entrez ID to STRING's ensembl protein ID.

139 ## <U+2714> Saving 'gene_ids' to 'data/gene_ids.rda'

140 Neuroexclusivity

Neuroexclusivity data consists of gene expression collected from Gexe Expression Atlas and the KEGG pathways themselves.

143 Expression neuroexclusivity

In this section we preprocess multiple wide .tsv files into a single long data.frame. We also create a template file for classifying tissues into nervous or non-nervous.

146 Resources

150

151

152

154

157

We start by searching Gene Expression Atlas for experiments that have human baseline expression data at the tissue level. For each experiment, TPM expression data is downloaded to the data-raw/download/gxa/directory. Found experiments:

- E-MTAB-513
- E-MTAB-2836
 - E-MTAB-3358
- E-MTAB-3708
 - E-MTAB-3716
 - E-MTAB-4344
- E-MTAB-4840
 - E-MTAB-5214

58 Reshaping data

159 We load and pivot all files to a long format.

```
gene_expression \( \) sapply(
    list.files("download/gxa/", full.names = T),
    read_tsv,
    comment = "#",
    simplify = FALSE,
    USE.NAMES = TRUE
)

# pivoting
gene_expression %\[ \%\ \\
    map_dfr(pivot_longer, cols = -(1:2), names_to = "tissue", values_to = "tpm") %\[ \%\ \\
    na.omit %\% \\
    select(ensembl_id = `Gene ID`, tissue, tpm)
```

50 Cleaning

A lot of tissue information can be collapsed into a single level (e.g. "brain" and "brain fragment" can be considered the same tissue). The cleaning is performed and expression data is exported for analysis.

```
## <U+2714> Setting active project to 'C:/R/neuro'
164 ## <U+2714> Saving 'gene_expression' to 'data/gene_expression.rda'
```

<pre>head(gene_expression)</pre>						
ensembl_id	tissue	tpm				
ENSG0000010379	adipose tissue	0.1				
ENSG00000010379	adrenal gland	0.1				
ENSG00000010379	cerebral cortex	5.0				
ENSG00000010379	colon	0.1				
ENSG00000010379	duodenum	5.0				
ENSG00000010379	fallopian tube	10.0				

Tissue classification

165

168

For subsequent analyses, we need to distinguish if a tissue is part of the nervous system or not. This is done by hand. The first step is to write a temp file to data-raw/temp/temp_tissue_classification.tsv with all tissue names. This serves as a base for the completed data/neuroexclusivity_classification_tissue file.

```
gene_expression %>%
  select(tissue) %>%
  unique %>%
  arrange %>%
  arrange %>%
  write_tsv("temp/temp_tissue_classification.tsv")
```

Pathway neuroexclusivity

171 In this section we create a template file for classifying pathways into nervous or non-nervous.

2 Resources

For link_pathway_entrez see Table 5.

Table 10: KEGG pathway names.

				pathway_names	
#	Col. name	Col. type	Used?	Example	Description
1	pathway_id	character	yes	path:hsa04726	KEGG pathway ID
2	pathway_name	character	yes	Serotonergic synapse - Homo sapiens (human)	pathway name

Location: data-raw/download/pathway_names.tsv Source: http://rest.kegg.jp/list/pathway/hsa

74 Pathway classification

Just like tissues, we need to distinguish if a pathway is related to the nervous system or not. This is done by hand. The first step is to write a temp file to data-raw/temp/temp_pathway_classification.tsv with all pathway names. This serves as a base for the completed data/neuroexclusivity_classification_pathway.tsv file.

```
# removing species prefix "hsa:"
link_pathway_entrez[["entrez_id"]] %◇% str_split_n("\\:", 2)
selected_genes_pathways ← link_pathway_entrez %>% filter(entrez_id %in% gene_ids[["entrez_id"]])
unique_pathway_ids ← selected_genes_pathways %>% pull(pathway_id) %>% unique
pathway_names %◇% filter(pathway_id %in% unique_pathway_ids) %>%
    mutate(is_nervous = NA) %>%
    write_tsv("temp/temp_pathway_classification.tsv")
```

Orthology data

This section refers to orthology data exported for geneplast use. Essentialy, we subset the global STRING mapping between proteins and orthologous groups into a smaller dataset containing only information about the orthogroups related to our selected genes.

Table 11: Orthologous groups (COGs, NOGs, KOGs) and their proteins.

				cogs	
#	Col. name	Col. type	Used?	Example	Description
1	$taxid.string_id$	character	yes	9606.ENSP00000269305	STRING protein ID
2	$start_position$	numeric	no	1	residue where orthogroup mapping starts
3	end_position	numeric	no	393	residue where orthogroup mapping ends
4	\cos _id	character	yes	NOG08732	orthologous group ID
5	protein_annotation	character	no	Cellular tumor antigen p53; []	protein description

Network Network

In this section we search the STRING API for our proteins of interest and recompute the combined interaction score.

189 Retrieving network data

Querying the API endpoint for the STRING IDs we collected.

```
identifiers \( \) gene_ids \( \) \( \) pull(string_id) \( \) \( \) \( \) na.omit \( \) \( \) pasteO(collapse="%0d") \)

if (!file.exists("download/string_ids.tsv")) {
    postForm(
        "http://string-db.org/api/tsv/get_string_ids"
        ,identifiers = identifiers
        ,echo_query = "1"
        ,species = "9606"
        ) \( \) \( \) \( \) \( \) write("download/string_ids.tsv") \)
}
```

Table 12: STRING interaction network with channel specific scores.

				string_ids	
#	Col. name	Col. type	Used?	Example	Description
1	queryItem	character	yes	ENSP00000258400	queried term
2	queryIndex	numeric	yes	266	index of queried term
3	$\operatorname{stringId}$	character	yes	9606.ENSP00000258400	STRING ID
4	ncbiTaxonId	numeric	yes	9606	NCBI Taxonomy ID
5	taxonName	character	yes	Homo sapiens	species name
6	preferredName	character	yes	HTR2B	common protein name
7	annotation	character	yes	5-hydroxytryptamine receptor 2B; []	protein annotation

Location: data-raw/download/string_ids.tsv

Source: http://string-db.org/api/tsv/get_string_ids

Now we need to make sure that the API successfully resolves the protein IDs we searched for.

```
api_ids \( \tau \) read_tsv("download/string_ids.tsv", comment = "", quote = "")

# removing taxid prefix
api_ids %\( \infty \) mutate(stringId = str_split_n(stringId, "\\.", 2))

# removing inexact matches (queried id is different from resolved id)
api_ids %\( \infty \) group_by(queryItem) %>% filter(queryItem = stringId)

# setequal must return true if ids matched exatcly
setequal(
    gene_ids %>% pull(string_id) %>% na.omit,
    api_ids %>% pull(stringId)
)
```

```
192 ## [1] TRUE
```

Once IDs are correct, we can query the network API endpoint to obtain the protein interaction edgelist.

```
# it is important to query this endpoint with the species prefix ("9606.")
identifiers 
    api_ids %>% pull(stringId) %>% na.omit %>% { pasteO("9606.", ., collapse="%0d") }

if (!file.exists("download/string_edgelist.tsv")) {
    postForm(
        "http://string-db.org/api/tsv/network"
        ,identifiers = identifiers
        ,species = "9606"
        ) %>%
        write("download/string_edgelist.tsv")
}
```

Table 13: STRING interaction network with channel specific scores.

string_edgelist						
#	Col. name	Col. type	Used?	Example	Description	
1	$stringId_A$	character	yes	ENSP00000215659	STRING ID (protein A)	
2	$stringId_B$	character	yes	ENSP00000211287	STRING ID (protein B)	
3	$preferredName_A$	character	yes	MAPK12	common protein name (protein A)	
4	$preferredName_B$	character	yes	MAPK13	common protein name (protein B)	
5	ncbiTaxonId	numeric	yes	9606	NCBI Taxonomy ID	
6	score	numeric	yes	0.948	combined score	
7	nscore	numeric	yes	0	gene neighborhood score	
8	fscore	numeric	yes	0	gene fusion score	
9	pscore	numeric	yes	0.014223	phylogenetic profile score

194 Recomputing scores

195 From string-db.org:

196

197

198

199

"In STRING, each protein-protein interaction is annotated with one or more 'scores'. Importantly, these scores do not indicate the strength or the specificity of the interaction. Instead, they are indicators of confidence, i.e. how likely STRING judges an interaction to be true, given the available evidence. All scores rank from 0 to 1, with 1 being the highest possible confidence."

For the sake of this project, we will only use experimental and database scores with a combined value >= 0.7, a high confidence threshold according to the STRING database. The combined score is given by the following expression, as stated in von Mering C et al, 2005:

$$S = 1 - \prod_i (1 - S_i)$$

```
string_edgelist \( \tau \) read_tsv("download/string_edgelist.tsv")

string_edgelist %\( \infty \) mutate(cs = combine_scores(., c("e","d"))) %>%
    filter(cs \( \geq 0.7) \) %>%
    select(stringId_A, stringId_B)

# how many edgelist proteins are absent in gene_ids (should return 0)
setdiff(
    string_edgelist %\( \frac{\stringId_A}{\stringId_A}, \stringId_B \right),
    gene_ids \( \frac{\stringId_A}{\stringId_B}, \stringId_B \right),
    gene_ids \( \frac{\stringId_A}{\stringId_B}, \stringId_B \right)

# exporting for package use
usethis::use_data(string_edgelist, overwrite = TRUE)
```

203 Analysis

204 Analysis

205 Root inference

To estimate the evolutionary root of a given gene, i.e. the ancestor from which its genetic archetype (orthologous group) is vertically inherited, we use orthologous group annotation from the STRING database. The presence and absence of orthologous groups in the species of a cladogram are used to determine its most likely ancestor. Loading initial resources:

```
library(tidyverse)
library(magrittr)
library(geneplast)
library(ape)
library(rentrez)
library(neurotransmissionevolution)

data(
    cogs,
    gene_cogs,
    string_eukaryotes,
    package = "neurotransmissionevolution"
)

phyloTree 
    read.tree("../data/hybrid_tree_modified.nwk") %>% rotatePhyloTree("9606")
```

We perform some minor data formatting before feeding it to geneplast

```
# formating cogdata column names for geneplast
cogs %<% rename(protein_id = string_id, ssp_id = taxid) %>% select(protein_id, ssp_id, cog_id)

# adding species names to taxid tree
phyloTree %<% list_modify(
   tip.alias = string_eukaryotes %$% string_name[match(phyloTree[["tip.label"]], taxid)]
)</pre>
```

Geneplast

Geneplast's groot.preprocess function structures an ogr object on which groot will perform the rooting.
We then retrieve the numeric root (groot.get("results")) for the cogs_of_interest, that is, orthologous groups pertaining to neurotransmission genes.

```
cogs_of_interest ← gene_cogs %>% pull(cog_id) %>% unique

ogr ← groot.preprocess(
    cogdata = cogs,
    phyloTree = phyloTree,
    spid = "9606",
    cogids = cogs_of_interest
)

roots ← groot(ogr, nPermutations = 1) %>%
    groot.get("results") %>%
    rownames_to_column("cog_id") %>%
    select(cog_id, root = Root)

write_tsv(roots, "geneplast_roots.tsv")

# setwd("plots/roots/")
# groot.plot(ogr, plot.lcas = TRUE, width=10, height=20, cex.lab = 0.2, cex.nodes = 0.4)
# setwd("../../")
```

Clade names

Each root branches to a clade that diverged from humans some time in the past. It is nice to have these clades taxonomically named to ease our interpretation. Unlike NCBI Taxonomy, TimeTree's internal nodes are not named. Therefore, we query the NCBI Taxonomy API to try to find most clade names automatically. It is important to note that we are using a hybrid tree primarily built from TimeTree data. This means NCBI Taxonomy naming will not perfectly match clades in our tree. For instance, root #36 branches to a clade containing 38 species from the SAR supergroup, but also 1 species from the Haptista rank, namely *Emiliania huxleyi*. The Haptista group is a sister clade to SAR, so it might be the case that *Emiliania huxleyi* is actually correctly placed together with SAR species by TimeTree, given their evolutionary proximity. Resolving these naming conflicts is not trivial and falls out of our scope.

```
sort(TRUE) %>%
    paste0(names(.), " (", .,")") %>%
    paste0(collapse="; ")) %>%
    mutate(clade_name = coalesce(clade_name, fallback_name)) %>%
    select(root, clade_name)
write_tsv(roots_names, "temp/temp_geneplast_clade_names.tsv")
```

225 Phyletic patterns

Visualizing the presence/absence matrix according to inferred roots and species' clades

```
lca_names ← read_tsv('geneplast_clade_names.tsv') %0% rename('lca' = root)
lca_ssp ← ogr@spbranches %0% rename('taxid' = ssp_id, 'species' = ssp_name, 'lca' = '9606')
# Saving for use in abundance computation
lca_ssp %0%
select(lca, taxid) %0%
mutate(taxid_order = row_number()) %0%
write_tsv('geneplast_clade_taxids.tsv')
cog_pam ← ogr@spthoct[,-1]
long_nam ←
```

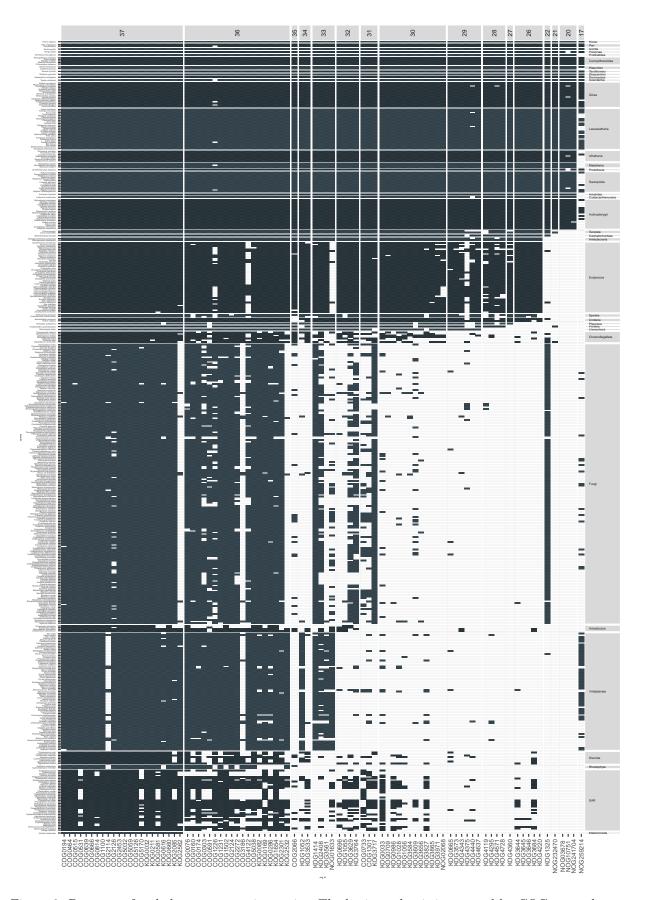

Figure 2: Presence of orthologous groups in species. The horizontal axis is grouped by COGs rooted at some specific LCA. The vertical axis is grouped by species' clades. A checkerboard pattern is superimposed to aid visual examination.

227 Neuroexclusivity

We characterize genes' relevance to the nervous system by inspecting what proportion of its activity is related to nervous processes. We relied on tissue RNA-Seq data, as well as KEGG's pathways themselves. Loading resources.

```
library(tidyverse)
library(magrittr)

data(
   gene_ids
   ,gene_pathways
   ,gene_expression
    ,package = "neurotransmissionevolution"
)
```

231 Expression neuroexclusivity

We start by averaging all gene_expression collected from the Expression Atlas by tissue (tpm_avg). The averaged expression is filtered for values greather than 0.5 TPM. This ensures further computations only account for tissues in which genes are actually expressed. Then, we add the manual tissue classification indicating which tissues are nervous or not (described in Preprocessing). The neuroexclusivity index for a gene is the sum of its tpm_avg values in nervous tissues divided by the sum its values in all tissues.

```
tissue_classification \( \) read_tsv(
    file = "../data/neuroexclusivity_classification_tissue.tsv"
    ,col_types = "ci"
)

# Averaging TPM expression by tissue
avg_by_tissue \( \) gene_expression %>%
    group_by(ensembl_id, tissue) %>%
    summarise(tpm_avg = mean(tpm)) %>%
    filter(tpm_avg \( \) 0.5) %>%
    left_join(tissue_classification)

# Measuring expression neuroexclusivity
expression_neuroexclusivity \( \) avg_by_tissue %>%
    group_by(ensembl_id) %>%
    summarise(expression_neuroexclusivity = sum(tpm_avg[is_nervous = 1])/sum(tpm_avg)) %>%
    write_tsv("neuroexclusivity_expression.tsv")
```

237 Pathway neuroexclusivity

To find the pathway neuroexclusivity of a gene, we simply divide the count of nervous pathways by the count of all pathways it participates in.

```
pathway_classification ← read_tsv(
    file = "../data/neuroexclusivity_classification_pathway.tsv"
    ,col_types = "cci"
)

link_pathway_entrez ← read_tsv(
    file = "../data-raw/download/link_pathway_entrez.tsv"
    ,col_names = c("entrez_id", "pathway_id")
    ,col_types = "cc"
)

# Removing "hsa:" prefix
link_pathway_entrez[["entrez_id"]] %◇% str_split_n("\\:", 2)

# Pathway data related to our genes of interest
selected_genes_pathways ← link_pathway_entrez %>%
    filter(entrez_id %in% gene_ids[["entrez_id"]]) %>%
    left_join(pathway_classification) %>%
    drop_na # Dropping general pathways

# Measuring pathway neuroexclusivity
```

```
pathway_neuroexclusivity ← selected_genes_pathways %>%
group_by(entrez_id) %>%
summarise(pathway_neuroexclusivity = sum(is_nervous)/length(is_nervous)) %>%
write_tsv("neuroexclusivity_pathway.tsv")
```

Network Network

²⁴¹ In this section we search the STRING API for our proteins of interest and recompute their combined interaction score.

243 Graph data

Loading resources.

Joining all gene data and creating the network graph object.

```
# If a gene has more than 1 COG, select the oldest one.
# This is unusual, but can happen in cases of gene fusion, for instance.
gene_cogs %<%
inner_join(cog_roots) %>%
group_by(string_id) %>%
filter(root = max(root)) %>%
inner_join(clade_names)

# Gathering all gene info available
vertices ← gene_ids %>%
na.omit %>%
inner_join(gene_pathways) %>%
inner_join(gene_annotation) %>%
```

```
inner_join(expression_neuroexclusivity) %>%
mutate(ne = pathway_neuroexclusivity ≥ 0.9) %>%
select(string_id, everything())

# Quick color hack to aid visualization
vertices %<>%
    unite(color, glutamatergic:dopaminergic, remove = F) %>%
    mutate(color = rainbow(color %>% n_distinct)[color %>% as.factor])

g ← graph_from_data_frame(string_edgelist, directed = F, vertices = vertices)

# Setting node sizes
V(g)$size ← V(g)$system_count %>% sqrt %>% multiply_by(5)
```

Generating the network layout (i.e. node coordinates).

```
if(file.exists("network_layout.tsv")) {
    layout ← read_tsv("network_layout.tsv", col_types = "dd") %>% as.matrix
} else {
    layout ← vivagraph(g, precompute_multiplier = 200, precompute_niter = 1000)
}

# inserting layout coordinates into graph object
V(g)$x ← layout[, 1]
# layout matrix comes vertically flipped
V(g)$y ← -layout[, 2]
```

²⁴⁷ Generating tidy edge coordinates for plotting.

```
# Recreating the vertices data.frame, now with layout coordinates (lazy)
vertices ← igraph::as_data_frame(g, what = "vertices") %>% rename(string_id = name)

# The edges data.frame will be used to draw lines with geom_line
edges ← string_edgelist %>%
    map(match, vertices[["string_id"]]) %>%
    map_dfr(~ vertices[.x,]) %>%
    select(x:y) %>%
    cbind(group = 1:nrow(string_edgelist))
```

Setting up reusable aesthetic parameters for the plots.

```
past_fill ← "#FFFFFF" # past nodes' fill color
past_color ← "#888888" # past nodes' border color
    vertices %<>% mutate(
          shape = ifelse(ne, "square filled", "circle filled"),
color_node = ifelse(ne, "#000000", element_colors[annotation] %>% darken(0.2)),
color_pie = ifelse(ne, "#000000", NA),
 # Some recurrent ggplot aesthetics
edge_aes ← aes(x = x, y = y, group = group)
text_aes ← aes(x = x, y = y, label = string_name)
pie_aes ← aes(x = x, y = y, group = string_id, r = size^(0.94) - 1.5)
          | The content of the 
           arrange(-root) %>%
             distinct(root, clade_name) %$%
set_names(root, clade_name)
```

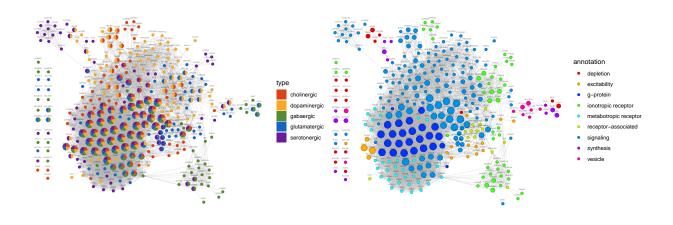

Figure 3: The human neurotransmission network with nodes colored by neurotransmitter systems (left) and neurotransmission functions (right).

```
ggsave("plots/fig1_raw.pdf", width = 14, height = 7, onefile = F, useDingbats = F)
```

```
# Retrieving the largest connected component
subgraphs ← decompose.graph(g)
lcc_index ← which.max(sapply(subgraphs, vcount))
```

The process for generating Figures 3 and 4 (as well as Supplementary Figures 2 and 3) is roughly the same. It consists of finding what nodes have numeric roots in a given range. In our analysis, the largest root is numbered 37 and represents the furthest human common ancestor in the cladogram (the Human-Metamonada LCA, as seen in previous sections). Root #1 is represented by *Homo sapiens* itself.

The nodes we need to draw are either current_nodes (roots in a specified numeric range), or past_nodes (roots > such specified range). The edges we need to draw are all edges between both sets of nodes.

Figure 3A

258

```
# Finding which genes should be drawn
current_genes 	 vertices %>% filter(root = 37)

# Finding which edges should be drawn
partial_ids 	 current_genes %>% pull(string_id)
which_edges 	 apply(string_edgelist, 1, function(r) all(r %in% partial_ids))
partial_edges 	 edges[which_edges,]

plot_edges 	 geom_path(
    data = partial_edges
    ,mapping = edge_aes
    ,color = edge_color
    ,size = 0.1
)

plot_text 	 geom_text(
```

```
data = current_genes
,mapping = text_aes
,size = 1
,vjust = 0
,nudge_y = 1.75
,alpha = 0.5
)

plot_current_pies \( \to \) geom_scatterpie(
    data = current_genes
,mapping = pie_aes
,cols = systems
,color = NA
)

# Assembling
fig3a \( \to \) ggplot() +
    plot_edges +
    plot_escales +

```

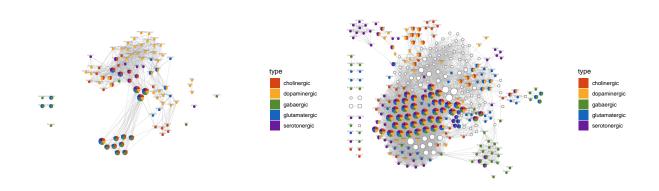

Figure 4: The human neurotransmission network with nodes colored by neurotransmitter systems and neurotransmission functions.

```
ggsave("plots/fig3_raw.pdf", width = 14, height = 7, onefile = F, useDingbats = F)
```

Additionally, we cumulatively count nodes by their categories (function and neuroexclusivity) and inferred root:

```
cumulative_emergence 		vertices %>%
    select(root, annotation, is_neuroexclusive = ne) %>%

# Adding clade info
    right_join(clade_names) %>%

# Pivoting from wide to long
    pivot_longer(annotation:is_neuroexclusive, values_ptypes = list(value = "character")) %>%

# Counting nodes by category (name) for each root
    count(root, clade_name, name, value) %>%

# Making absent counts explicit
    group_by(name) %>%

complete(nesting(root, clade_name), name, value, fill = list(n = 0)) %>%

# No reason to include NA observations in cumulative sum
    na.omit %>%

# Cumulative sum node count at each root
    group_by(name, value) %>%

mutate(cumulative_count = order_by(-root, cumsum(n)))
```

264 Plotting such cumulative counts:

```
cumulative_emergence % % ungroup % %

# Creating ordered factors for plotting
mutate(
   clade_name = fct_reorder(clade_name, -root)
   ,value = fct_reorder(value, name)
)

ggplot(cumulative_emergence) +

#---- Barplot -----

    grepl("clearance", annotation) ~ "depletion"
,grepl("degradation", annotation) ~ "depletion"
    ,grepl("transport", annotation) ~ "synthesis"
```

We start by setting up reusable data frames with useful metrics.

```
gene_cogs %⇔%
 inner_join(cog_roots) %>%
 group_by(string_id) %>%
cog_annotation ← gene_ids %>%
 inner_join(gene_cogs) %>%
 distinct(cog_id, annotation)
cog_size_by_taxid ← cogs %>%
 filter(cog_id %in% gene_cogs[["cog_id"]]) %>%
 count(taxid, cog_id, name = "cog_size")
cog_n_by_taxid ← cog_size_by_taxid %>%
  count(taxid, name = "cog_n")
```

Abundance is finally computed as the number of proteins pertaining to a function divided by the number of neurotransmission COGs in a species.

```
abundance_by_function \( \simeq \cog_size_by_taxid \%>\%
inner_join(cog_annotation) \%>\%
count(taxid, annotation, wt = cog_size, name = "annotation_count") \%>\%
left_join(cog_n_by_taxid) \%>\%
left_join(protein_n_by_taxid) \%>\%
mutate(
    abundance = annotation_count / cog_n
    ,abundance_prop = annotation_count / protein_n
)
```

282 Plotting:

Figure 8: Abundance values by species. Species are ordered like in Supplementary Figure S1.

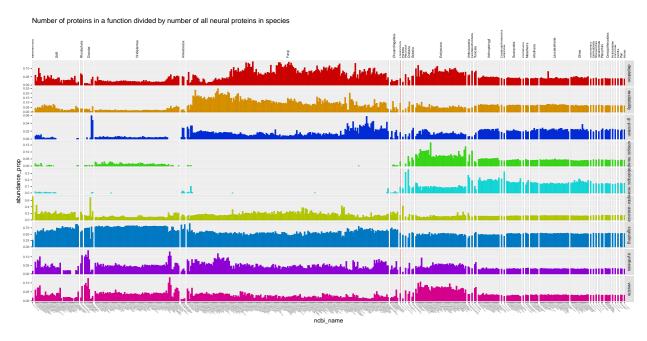

Figure 9: Abundance values by species. Species are ordered like in Supplementary Figure S1.

```
ggsave("plots/fig5_prop_raw.pdf", width = 16, height = 8)
```

83 Abundances averaged by clades.

```
ggplot(abundance_by_function) +
  geom_bar(aes(x = clade_name, y = abundance, fill = annotation), stat="summary", fun = "mean") +
  scale_fill_manual(values = annotation_colors, guide = "none") +
  facet_grid(annotation ~ ., scales = "free") +
  theme(
    panel.spacing = unit(1, "pt")
    ,strip.text.y = element_text(angle = 0, hjust = 0)
    ,axis.text.x = element_text(size = 5, angle = -45, vjust = 0, hjust = 0)
    ,axis.text.y = element_text(size = 5)
)
```

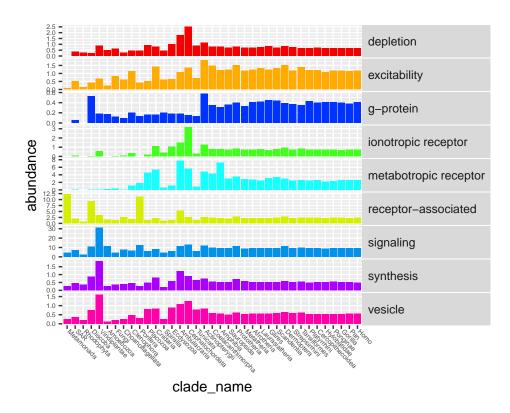

Figure 10: Abundances averaged by clades.

Breaking the data even further into the number of proteins in each neurotransmission COG.

```
# Merging mixed COG functions
cog_annotation_collapsed 
    cog_annotation = paste(annotation, collapse = "/"))
# Adding colors for mixed COGs
annotation_colors %c% c(
    "vesicle/synthesis" = "#808080"
    ,"depletion/vesicle" = "#808080"
    ,"signaling/excitability" = "#808080"
    )
# Simply joining cog annotation and sizes
protein_count_by_cog ← cog_size_by_taxid %c%
    inner_join(cog_annotation) %c%
    inner_join(cog_annotation) %c%
    inner_join(cog_annotation) %c%
    inner_join(cog_annotation) %c%
    inner_join(cod_annotation) %c%
    mutate(cog_id = fct_inorder(cog_id))
##gom_bar(ase(x = ncbi_name, y = cog_size, fill = annotation), stat = "identity") +
    scale_fill_manual(values = annotation_colors %c% darken(0.2), guide = "none") +
    scale_fill_manual(values = annotation_colors %cderken(0.2), guide = "none") +
    scale_f_continuous(breaks = tick_function(3, 1), minor_breaks = NULL) +
    facet_grid(cog_id ~ ., scales = "free_y") +
    theme(
        panel_spacing = unit(0.5, "pt")
        ,panel_grid.major.x = element_blank()
        ,panel_grid.major.y = element_line(size = 0.1, linetype = "dashed")
        ,strip.text.y = element_text(size = 4, angle = 0, hjust = 0)
        ,axis.text.x = element_text(size = 4, angle = -45, vjust = 0, hjust = 0)
        ,axis.text.y = element_text(size = 1.5, angle = -45, vjust = 0, hjust = 0)
        ,axis.text.y = element_text(size = 4)
        ,axis.text.y = element_line(size = 0.1)
}
```

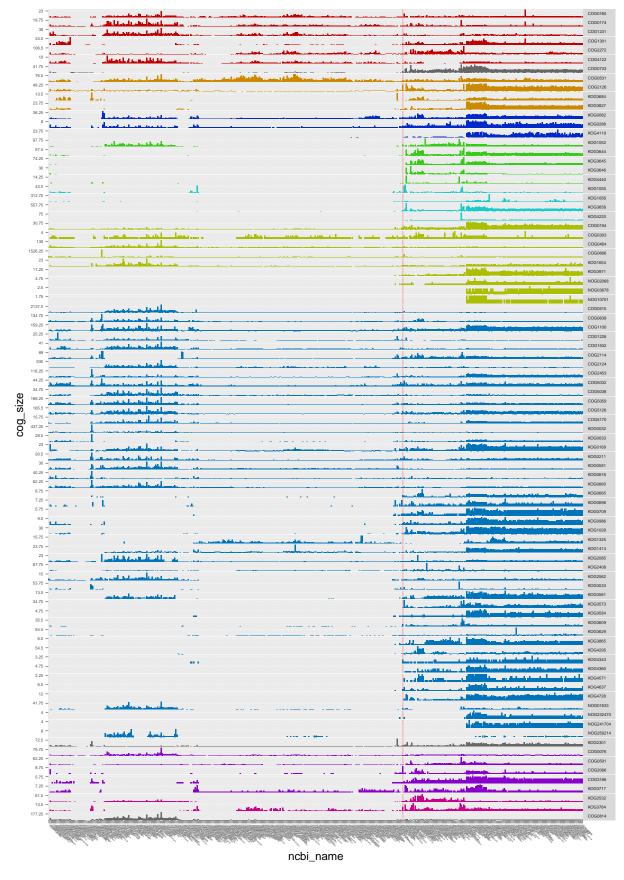

Figure 11: Number of proteins in each neurotransmission COG, for every species.
